

CloudXeus Security and Compliance Handbook

Internal and Customer-Facing Security Guidance - May 2026

Security Operating Principles

CloudXeus follows a least-privilege operating model. Customer environments must be accessed through approved identities, approved devices, and approved support processes. Shared accounts are not permitted for administrative activity.

- Privileged access must use named accounts and multifactor authentication.
- Production access should be time-bound and reviewed after completion of the support activity.
- Secrets must be stored in approved secret stores such as Azure Key Vault and must not be copied into tickets or chat messages.
- Customer data must not be used in demonstrations unless it has been approved and sanitized.

Data Handling Rules

Support engineers may collect logs, screenshots, and diagnostic exports only when needed for troubleshooting. Sensitive personal data should be minimized, masked, or excluded when possible.

CloudXeus retains support ticket attachments for 180 days by default unless a customer contract specifies a shorter retention period. Security incident records are retained for 365 days.

Generative AI Usage

CloudXeus permits generative AI tools for drafting, summarization, and internal knowledge retrieval when customer confidentiality controls are followed. Customer secrets, authentication tokens, private keys, and unapproved personal data must not be entered into public AI tools.

For RAG applications, the preferred architecture is to keep customer content in approved Azure resources and use retrieval grounding rather than embedding sensitive content directly in system prompts.

Audit and Monitoring Expectations

- Administrative actions in customer subscriptions must be logged.
- Critical alerts should be routed to the support queue and the service delivery manager.
- Agent and application traces should avoid storing full secrets or unnecessary customer data.
- Access reviews are required at least quarterly for long-running support engagements.
